Introduction

The web application “Cost Benefit Analysis for Regional Weed Management” enables a cost-benefit analysis to be conducted for a Weed Management Programme proposed for inclusion in a Regional Management Plan as required by the New Zealand Biosecurity Act 1993. It is suitable for any of the four species-led programme types defined in the National Policy Direction for Regional Pest Management: Exclusion; Eradication; Progressive Containment; Sustained Control. The model assumes that the weed would spread logistically in the absence of the programme (“No Management”) and that “Management” would prevent this spread. The costs associated with both the “No Management” and “Management” cases and the difference, the Net

Present Value, are defined in the next three sections. In the remaining section “Weed Management Programme Types” we define the invasion trajectories with and without management for each of the four species-led programme types. The details of the model along with a worked example for a “containment” programme (now defined as Sustained Control) are published in the New Zealand Journal of Agricultural Research (Bourdôt *et al.*, 2015).

No Management

The total area of the land management units that would be occupied by the weed in the absence of the proposed weed management programme is $A_{NM}(t)$ hectares in year t . The costs (\$/ha) of lost production due to the infestation on these land management units in year t are

$$C_{NM}(t) = A_{NM}(t) \times \text{cash operating surplus} \times f$$

where f is the percentage reduction in cash operating surplus (\$/ha) due to the presence of the weed.

The total costs are the annual costs discounted (with a discount rate i) and summed over the time frame chosen for the analysis $t = 0$ to $t = t_{\max}$ years:

$$TC_{NM} = \sum_{t=0}^{t=t_{\max}} C_{NM}(t) \times (1+i)^{-t}$$

Management

$A_M(t)$ is the land area (ha) of the infestation in year t in the presence of management. The implementation costs $I(t)$ and lost production costs (\$/ha) due to the infestation are

$$C_M(t) = A_M(t) \times \text{cash operating surplus} \times f.$$

The total costs are the annual costs discounted (discount rate i) and summed over the time frame $t = 0$ to $t = t_{\max}$ years.

$$TC_M = \sum_{t=0}^{t=t_{\max}} (C_M(t) + I(t)) \times (1+i)^{-t}.$$

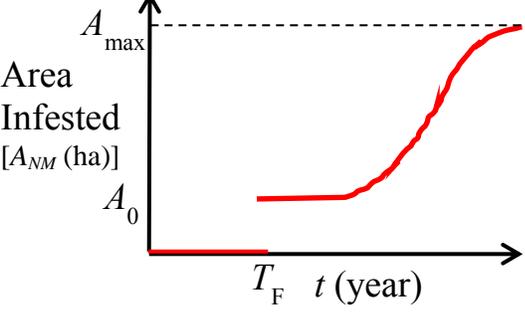

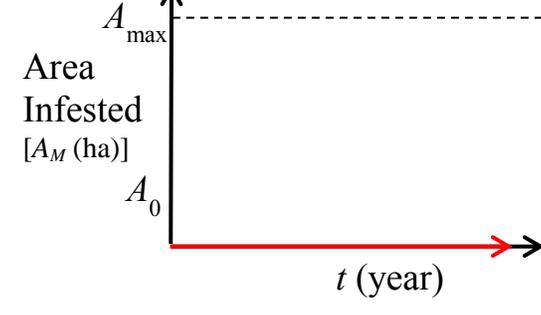

Net Present Value of the weed management programme

The NPV is the difference between the total costs for no management and management:

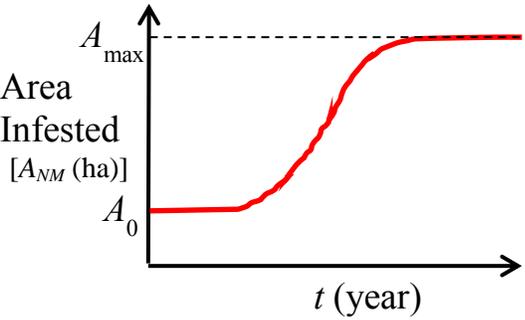

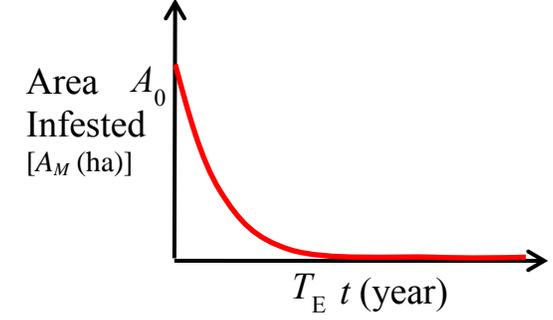

$$NPV = TC_{NM} - TC_M$$

Weed Management Programme Types

1. Exclusion

No management	Management	
 <p>Area Infested [A_{NM} (ha)]</p> <p>After T_F years of absence, the weed is found to occupy an area of A_0 hectares. The weed then spreads logistically:</p> $A_{NM}(t) = \frac{A_0 A_{\max}}{A_0 + (A_{\max} - A_0)e^{-r(t-t_F)}}$ <p>where A_{\max} is the maximum infested area and</p> $r = \frac{-1}{T_{90}} \times \ln\left(\frac{A_0(1/0.9 - 1)}{A_{\max} - A_0}\right)$ <p>where T_{90} is the time (years) needed to reach 90% of the maximum infested area.</p>	 <p>Area Infested [A_M (ha)]</p> <p>$A_M(t) = 0$</p>	Exclusion

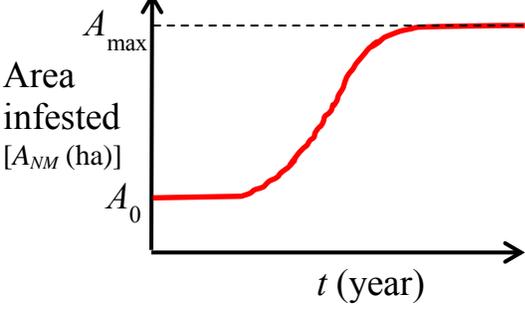

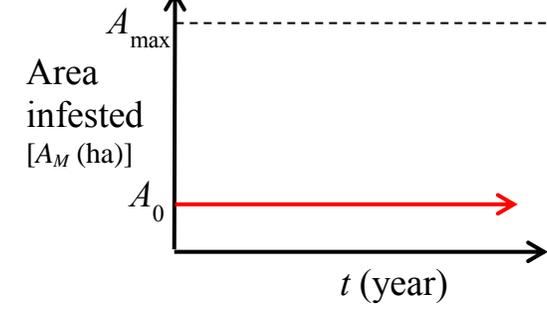

2. Eradication

No management	Management	
 <p style="text-align: center;">$A_{NM}(t) = \frac{A_0 A_{\max}}{A_0 + (A_{\max} - A_0)e^{-rt}}$</p>	 <p>The weed spreads according to the equations</p> $A_M(t) = \begin{cases} \frac{A_0 A_{\max}}{A_0 + (A_{\max} - A_0)e^{-rt}} & t < T_E \\ 0 & t \geq T_E \end{cases}$ <p>where A_0 is the initial infested area, A_{\max} is the maximum infested area and</p> $r = \frac{-1}{T_E} \times \ln \left(\frac{A_{\max} - pA}{p(A_{\max} - A_0)} \right) < 0$ <p>where T_E is the time (years) to reach eradication. Eradication is defined here as the time (years) needed to reach $p = 0.01\%$ of the initial infested area.</p>	Eradication

3. Progressive containment

No management	Management	
<div data-bbox="175 415 706 724" data-label="Figure"> <p>The graph shows the area infested over time without management. The y-axis is labeled 'Area infested [A_{NM} (ha)]' and has markers for A₀ and A_{max}. The x-axis is labeled 't (year)'. A red curve starts at A₀ on the y-axis and increases, following a sigmoidal path, asymptotically approaching A_{max} as time increases.</p> </div> <div data-bbox="186 840 641 934" data-label="Equation-Block"> $A_{NM}(t) = \frac{A_0 A_{\max}}{A_0 + (A_{\max} - A_0)e^{-rt}}$ </div>	<div data-bbox="787 420 1339 745" data-label="Figure"> <p>The graph shows the area infested over time with management. The y-axis is labeled 'Area infested [A_M (ha)]' and has markers for A₀ and A₁. The x-axis is labeled 'T_C t (year)'. A red curve starts at A₀ on the y-axis and decays exponentially towards a horizontal asymptote at A₁ as time increases.</p> </div> <div data-bbox="730 829 1323 871" data-label="Text"> <p>The weed spreads according to the equations:</p> </div> <div data-bbox="730 871 1218 976" data-label="Equation-Block"> $A_M(t) = \begin{cases} A_1 + (A_0 - A_1)e^{-rt}, & t < T_C \\ A_1, & t \geq T_C \end{cases}$ </div> <div data-bbox="730 976 1323 1050" data-label="Text"> <p>where A₁ is the desired area within which the weed is to be contained, A₀ is the initial</p> </div> <div data-bbox="730 1050 1339 1144" data-label="Text"> <p>infested area (ha) and $r = \frac{-1}{T_C} \times \ln(p)$ where</p> </div> <div data-bbox="730 1144 1339 1312" data-label="Text"> <p>T_C is the time (years) to reach containment. Containment is defined here as the time (years) needed to reach A₁ + p × (A₀ - A₁) with p = 0.01%.</p> </div>	<p>Progressive containment</p>

4. Sustained control

No management	Management	
 <p data-bbox="186 472 316 588">Area infested [A_{NM} (ha)]</p> <p data-bbox="495 672 609 714">t (year)</p> $A_{NM}(t) = \frac{A_0 A_{\max}}{A_0 + (A_{\max} - A_0)e^{-rt}}$	 <p data-bbox="732 472 862 588">Area infested [A_M (ha)]</p> <p data-bbox="1063 672 1177 714">t (year)</p> <p data-bbox="732 808 1218 892">The weed spreads according equation $A_M(t) = A_0$</p>	<p data-bbox="1388 394 1429 640">Sustained control</p>
